

# Computer Systems

## #8. Instructions (Control Transfer)

Keiji Kimura <keiji@waseda.jp>

## Ans. for Exercise (1)

---

- ▶ Translate following expression into MIPS assembly language, then encode into machine code under the assumption that \$t1 has the base of the array A and \$s2 corresponds to h:
  - ▶ `A[300] = h+A[300]; /* All variables are 32bit integer */`
    - ▶ TBA
- ▶ Exploit rt field into \$t1 when \$s0 has an instruction code.
  - ▶ TBA

# branch

---

- ▶ **Conditional branch**
  - ▶ Based on the condition at that time, jump to other instructions
- ▶ **MIPS has two conditional branch instructions**
  - ▶ `beq register1, register2, LI`
    - ▶ Jump to LI if register1 equals to register2
  - ▶ `bne register1, register2, LI`
    - ▶ Jump to LI if register 1 doesn't equal to register2

# PC relative addressing

- ▶ PC (program counter)
  - ▶ contains the address of the current instruction.
- ▶ beq and bne are I-format

- ▶ immediate has only 16bits width
  - ▶ Not enough for representing an instruction address (32bits)
- ▶ PC relative addressing
  - ▶ Target address is calculated as  $(PC+4)+immediate*4$ .
    - ▶ immediate is signed value.
    - ▶ Why  $(PC+4)$ ? Why  $immediate*4$ ?
- ▶ j (jump instruction)
  - ▶ J-format (26bits)
  - ▶ “address” represents target address (in word address)

# MIPS Addressing Mode Summary

---

- ▶ Addressing modes
  - ▶ multiple forms of addressing
- ▶ MIPS addressing modes
  - ▶ Immediate addressing
    - ▶ The operand is a constant within the instruction itself. (I-format)
  - ▶ Register addressing
    - ▶ The operand is a register. (R-format)
  - ▶ Base or displacement addressing
    - ▶ The operand is at the memory location whose address is the sum of a register and a constant in the instruction. (lw/sw)
  - ▶ PC-relative addressing
    - ▶ The branch address is the sum of the PC and a constant in the instruction.
  - ▶ Pseudo direct addressing
    - ▶ The jump address is the 26bits of the instruction concatenated with the upper bits of the PC. (J-format)

## if-then-else in MIPS assembly

---

- ▶ ex.) if (i==j) f = g+h; else f=g-h;
- ▶ Five variables f through j correspond to the five registers \$s0 through \$s4
- ▶     bne \$s3,\$s4, Else # if  
      add \$s0, \$s1, \$s2 # then part  
      j Exit  
Else:  
      sub \$s0, \$s1, \$s2 # else part  
Exit:

# Loops in MIPS assembly

---

- ▶ Important operation for iterative computations
- ▶ ex) while (save[i] == k) i++;
- ▶ i and k correspond to register \$s3 and \$s5 and the base of the array save is in \$s6
- ▶ Loop:
  - sll \$t1, \$s3, 2 # i\*4 for save[i] (32bit data)
  - add \$t1, \$t1, \$s6
  - lw \$t0, 0(\$t1)
  - bne \$t0, \$s5, Exit # (save[i] != k)?
  - addi \$s3, \$s3, 1
  - j Loop
- Exit:

# Comparison

---

- ▶ beq and bne are for evaluating equality.
- ▶ How about less than and larger than?
- ▶ slt: set on less than
  - ▶ `slt $t0, $s3, $s4` # `$t0 = 1` if `$s3 < $s4`
- ▶ slti
  - ▶ `slti $t0, $s3, 10` # `$t0 = 1` if `$s3 < 10`
- ▶ sltu/sltiu
  - ▶ for unsigned integers
- ▶ How to represent other relative conditions?
  - ▶ less than or equal, greater than, greater than or equal
- ▶ Why not blt?

## Exercise (1)

---

- ▶ Show assembly code for the following loop under the assumption  $i$  corresponds to register  $\$s3$  and the base of the array “save” is in  $\$s6$ .
  - ▶ for ( $i = 0; i < 10; i++$ )  $\text{save}[i] = 0$ ;
- ▶ Show assembly code for the following statements under the assumption  $f$  through  $j$  correspond to the five registers  $\$s0$  through  $\$s4$ .
  - ▶ if ( $i \leq j$ )  $f = g + h$ ; else  $f = g - h$ ;
- ▶ Suppose register  $\$s0$  has the hexadecimal number  $0xffffffff$  and the register  $\$s1$  has 1. What are the values of register  $\$t0$  and  $\$t1$  after the following instructions?
  - ▶  $\text{slt } \$t0, \$s0, \$s1$   
    $\text{sltu } \$t1, \$s0, \$s1$

# Procedure (function) call steps

---

- ▶ An important tool programmers use to structure programs
- ▶ Go to the procedure, back to the calling point with results, then continue to process after the calling point.
- ▶ procedure execution steps:
  - ▶ Put parameters in a place where the procedure can access them.
  - ▶ Transfer control to the procedure.
  - ▶ Acquire the storage resources needed for the procedure.
  - ▶ Perform the desired task.
  - ▶ Put the result value in a place where the calling program can access it.
  - ▶ Return control to the point of origin, since a procedure can be called from several points in a program.

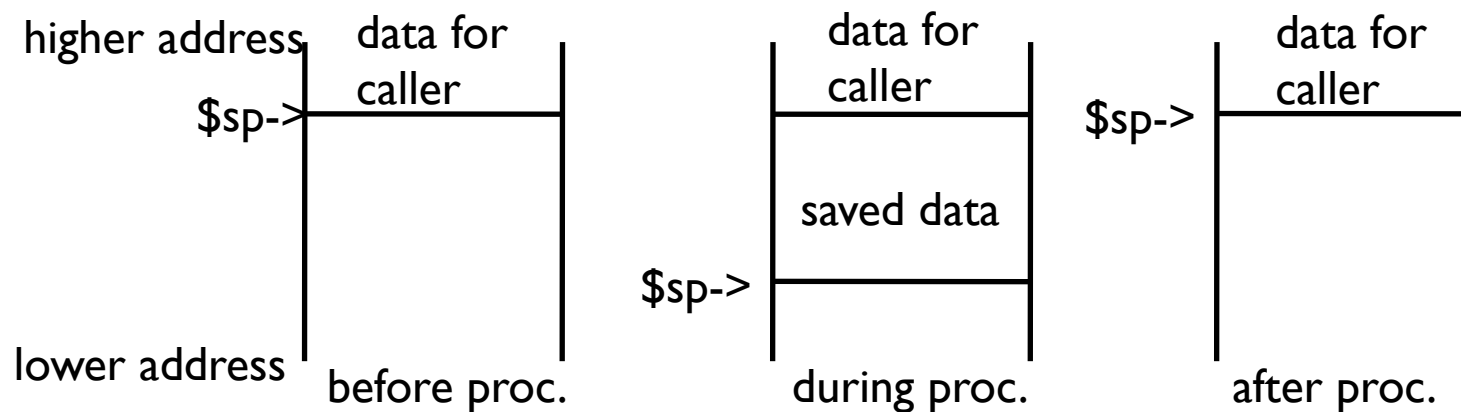

# Simple function call and return

---

- ▶ Set arguments to register \$a0-\$a3.
  - ▶ How about arguments more than five?
- ▶ jal ProcedureAddress
  - ▶ jump-and-link
  - ▶ Jumps to an address and simultaneously saves the address of the following instruction (PC+4) in register \$ra.
- ▶ Set results to register \$v0-\$v1.
- ▶ jr \$ra
  - ▶ jump register
  - ▶ Jumps to the address stored in register \$ra.

# More registers

- ▶ To use other registers than `$a0-$a3` and `$v0-$v1`
  - ▶ Save values in registers before procedure processing, and restore them after procedure processing.
  - ▶ Stack is used for this purpose.
    - ▶ push: save data onto the stack
    - ▶ pop: restore (and remove) from the stack
    - ▶ stack pointer: the pointer holding the stack top address
      - The register `$sp` in MIPS

## ex) procedure body with push/pop

- ▶ 

```
int leaf_example(int g, int h, int i, int j)
{
    int f; /* corresponds $s0 */
    f = (g+h)-(i+j);
    return f;
}
```
- ▶ 

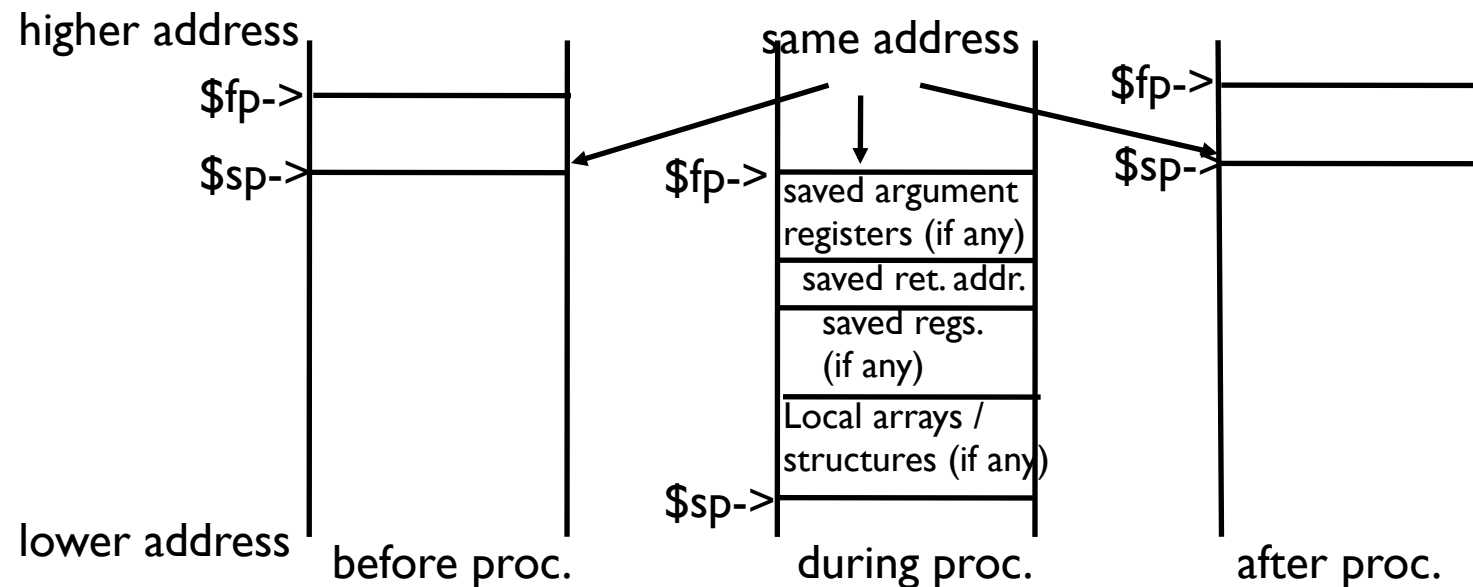

```
leaf_example:
    addi $sp, $sp, -12 # adjust stack to make room for 3 items
    sw   $t1, 8($sp)   # push values
    sw   $t0, 4($sp)
    sw   $s0, 0($sp)
    add  $t0, $a0, $a1 # proc. body
    add  $t1, $a2, $a3
    sub  $s0, $t0, $t1
    add  $v0, $s0, $zero # returns f ($v0 = $s0+0)
    lw   $s0, 0($sp)   # pop vaules
    lw   $t0, 4($sp)
    lw   $t1, 8($sp)
    addi $sp, $sp, 12  # adjust stack to delete 3 items
    jr   $ra # back to calling point
```
- ▶ Actually, \$t0-\$t9 need not to save by the callee (called procedure) in MIPS convention.

# Nested procedure call

- ▶ How about further procedure calls, such as recursive calls?
  - ▶ All execution context, including \$ra, \$sp and other registers, must be saved onto the stack.
- ▶ `int fact(int n)`
  - `{`
  - `if (n < 1) return 1;`
  - `else return (n*fact(n-1));`
  - `}`
- ▶ `fact:`
  - `addi $sp, $sp, -8 # adjust stack for 2 items`
  - `sw $ra, 4($sp) # save the return address`
  - `sw $a0, 0($sp)`
  - `slti $t0, $a0, 1 # test for n < 1`
  - `beq $t0, $zero, LI`
  - `addi $v0, $zero, 1 #return 1`
  - `addi $sp, $sp, 8 # pop 2 items off stack`
  - `jr $ra`
- `LI:`
  - `addi $a0, $a0, -1`
  - `jal fact`
  - `lw $a0, 0($sp) # return from jal`
  - `lw $ra, 4($sp)`
  - `addi $sp, $sp, 8`
  - `mul $v0, $a0, $v0 # return n*fact(n-1)`
  - `jr $ra`

# Procedure frame (Activation record)

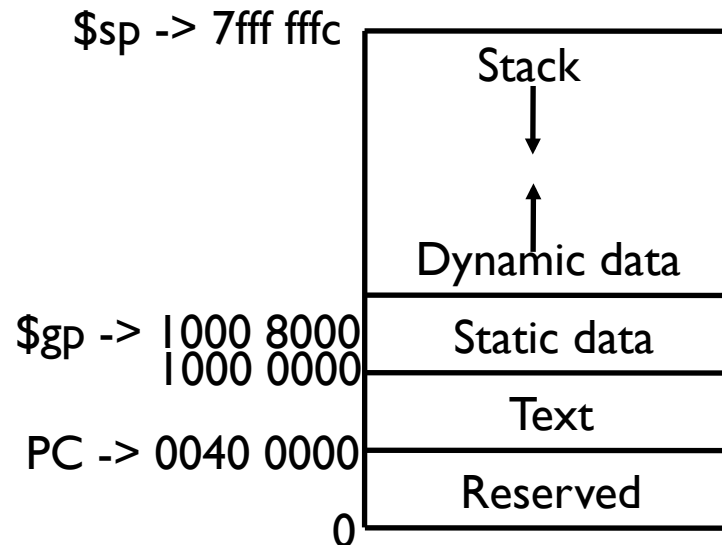

- ▶ Procedure local variables, which do not fit in registers, are also stored in the stack.
- ▶ Procedure frame (Activation record)
  - ▶ the stack containing a procedure's saved registers and local variables
  - ▶ \$fp (frame pointer): pointing to the first word of the frame of a procedure.

# Global variables and Heap objects

---

- ▶ Global variables and static variables in C
  - ▶ the register `$gp` (global pointer) is used to access these data in MIPS.
- ▶ Dynamically allocated objects are from heap area.
  - ▶ `malloc()` in C, `new` in Java
  - ▶ Following is MIPS memory map.

## Exercise (2)

---

- ▶ Rewrite assembly code for fact using \$fp.
- ▶ Then, show the procedure frame before and after the 2<sup>nd</sup> calling of fact.
